

# Python Flow Control

- **if...else**
- **for Loop**
- **while loop**
- **Break and continue**
- **Pass statement**

## if statement

- In computer programming, the **if statement** is a conditional statement.
- It is used to execute a block of code only when a specific condition is met.

### **For example,**

Suppose we need to assign different grades to students based on their scores.

- 1.If a student scores above 90, assign grade A
- 2.If a student scores above 75, assign grade B
- 3.If a student scores above 65, assign grade C

These conditional tasks can be achieved using the if statement.

An if statement executes a block of code only when the specified condition is met.

## Syntax

if condition:

    # body of if statement

- If condition evaluates to **True**, the body of the if statement is executed.
- If condition evaluates to **False**, the body of the if statement will be skipped from execution.

## Condition is True

```
number = 10
```

```
if number > 0:  
    # code
```

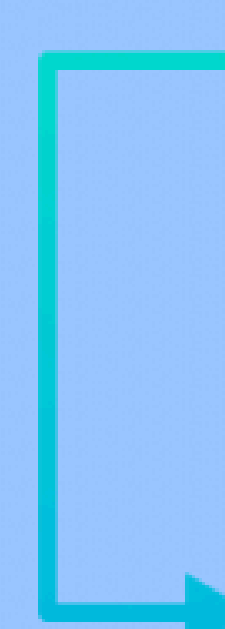

```
# code after if
```

## Condition is False

```
number = -5
```

```
if number > 0:  
    # code
```

```
# code after if
```

- If user enters 10, the condition `number > 0` evaluates to True. Therefore, the body of if is executed.
- If user enters -5, the condition `number > 0` evaluates to False. Therefore, the body of if is skipped from execution

## Indentation in Python

- **Python uses indentation to define a block of code, such as the body of an if statement.**

```
x = 1
```

```
total = 0
```

```
# start of the if statement
```

```
if x != 0:
```

```
    total += x
```

```
    print(total)
```

```
# end of the if statement
```

Here, the body of if has two statements. We know this because two statements (immediately after if) start with indentation. We usually use four spaces for indentation in Python, although any number of spaces works as long as we are consistent.

You will get an error if you write the above code like this:

```
# Error code
```

```
x = 1
```

```
total = 0
```

```
if x != 0:
```

```
total += x
```

```
print(total)
```

# Python if...else Statement

An if statement can have an optional else clause. The else statement executes if the condition in the if statement evaluates to False.

## Syntax

if condition:

    # body of if statement

else:

    # body of else statement

Here, if the condition inside the if statement evaluates to

- **True** - the body of if executes, and the body of else is skipped.
- **False** - the body of else executes, and the body of if is skipped

**Condition is True**

```
number = 10
if number > 0:
    # code

else:
    # code

# code after if
```

**Condition is False**

```
number = -5
if number > 0:
    # code

else:
    # code

# code after if
```

## **if...elif...else Statement**

- The if...else statement is used to execute a block of code among two alternatives.
- However, if we need to make a choice between more than two alternatives, we use the if...elif...else statement.

### **Syntax**

if condition1:

    # code block 1

elif condition2:

    # code block 2

else:

    # code block 3

### 1st Condition is True

```
let number = 5
if number > 0 :
    # code
elif number < 0 :
    # code
else :
    # code
# code after if
```

A flowchart illustrating the execution of an if-elif-else statement when the first condition is true. It starts with the variable 'number' set to 5. A teal arrow points from the 'if number > 0 :' line to the '# code' block. Another teal arrow points from the end of the 'else' block down to the '# code after if' line, bypassing the 'elif' block.

### 2nd Condition is True

```
let number = -5
if number > 0 :
    # code
elif number < 0 :
    # code
else :
    # code
# code after if
```

A flowchart illustrating the execution of an if-elif-else statement when the second condition is true. It starts with the variable 'number' set to -5. A teal arrow points from the 'elif number < 0 :' line to its corresponding '# code' block. Another teal arrow points from the end of the 'else' block down to the '# code after if' line, bypassing the 'if' block.

### All Conditions are False

```
let number = 0
if number > 0 :
    # code
elif number < 0 :
    # code
else :
    # code
# code after if
```

A flowchart illustrating the execution of an if-elif-else statement when all conditions are false. It starts with the variable 'number' set to 0. A teal arrow points from the 'else :' line to its corresponding '# code' block. Another teal arrow points from the end of the 'else' block down to the '# code after if' line.

# Python Nested if statements

It is possible to include an if statement inside another if statement. For example,

```
number = 5

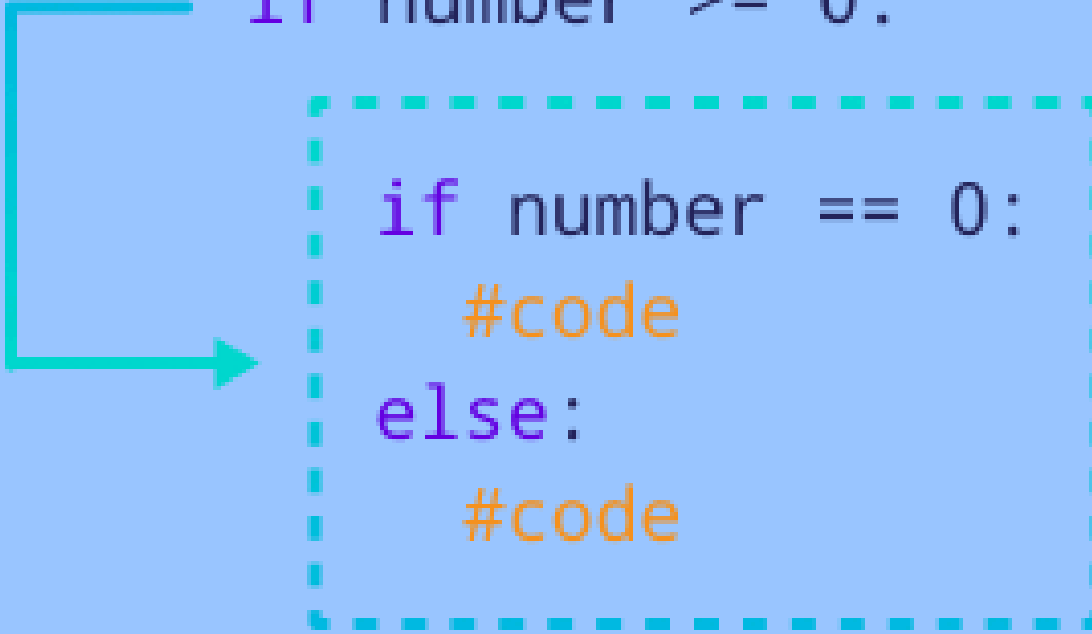

# outer if statement
if number >= 0:
    # inner if statement
    if number == 0:
        print('Number is 0')

    # inner else statement
    else:
        print('Number is positive')

# outer else statement
else:
    print('Number is negative')
```

## Outer if Condition is True

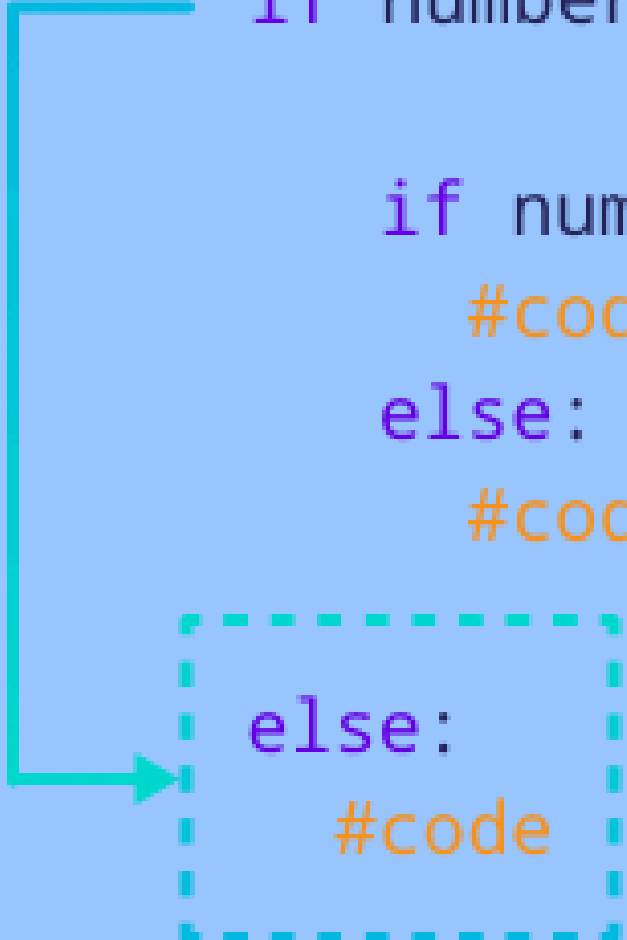

```
number = 5  
  
if number >= 0:  
    if number == 0:  
        #code  
    else:  
        #code  
else:  
    #code
```

The diagram illustrates the execution flow for the 'Outer if Condition is True' scenario. A teal arrow originates from the 'if number >= 0:' line and points into a dashed teal box that encloses the nested 'if number == 0:' block. This indicates that the outer condition is satisfied, and the program enters the 'if' block to evaluate the inner condition.

## Outer if Condition is False

```
number = -5  
  
if number >= 0:  
    if number == 0:  
        #code  
    else:  
        #code  
else:  
    #code
```

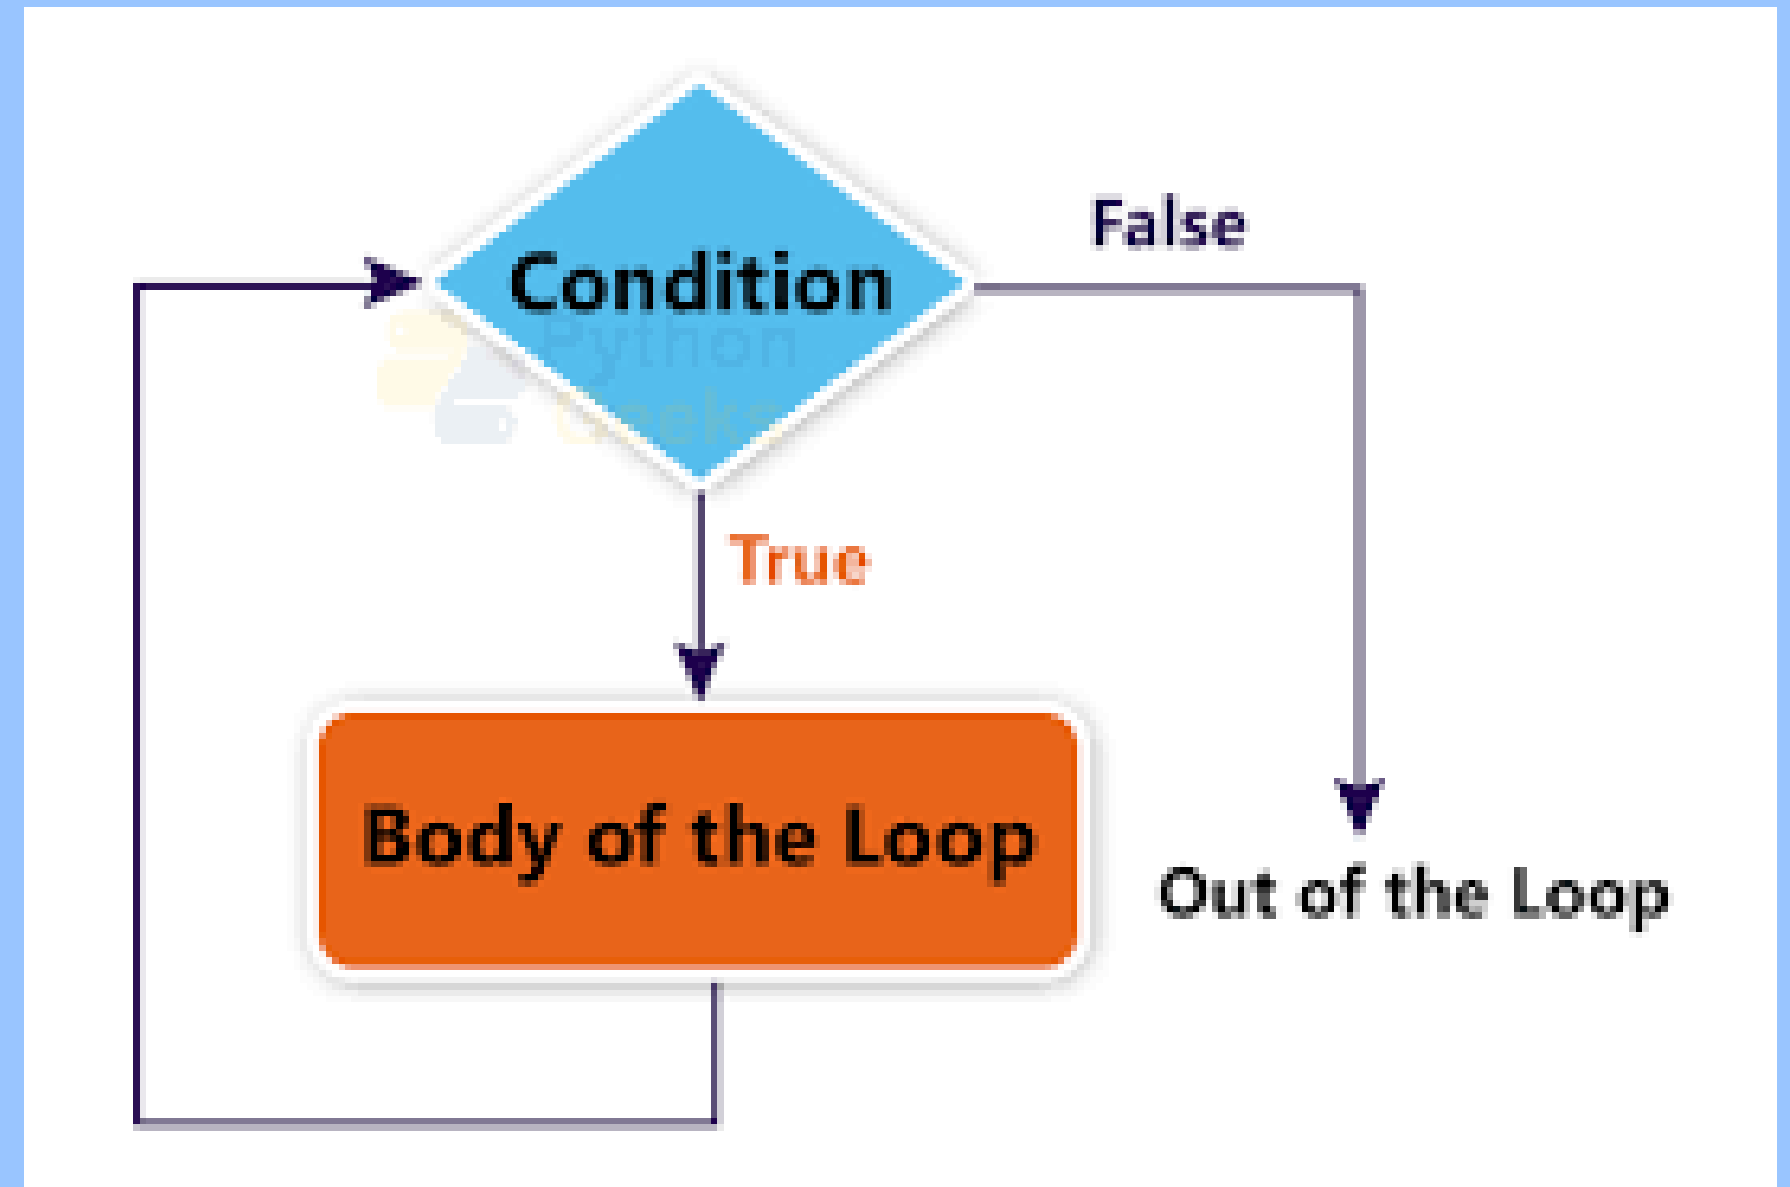

The diagram illustrates the execution flow for the 'Outer if Condition is False' scenario. A teal arrow originates from the 'if number >= 0:' line and points into a dashed teal box that encloses the 'else:' block. This indicates that the outer condition is not satisfied, and the program skips the nested 'if' block to execute the 'else:' block.

# Loops

- Loops are used in programming to repeat a specific block of code.

## Looping Constructs in Python

- **While**
- **for**

# While Loop

- The while loop in python is used to iterate over a block of code as long as the test expression (condition) is true.
- We generally use this loop when we don't know the number of times to iterate

## Syntax

while condition:

    # code to execute

Condition is a boolean expression that determines whether the loop should continue or not.

For example, let's say we want to print the number from 1 to 5 using a while loop:

```
num = 1
while num <= 5:
    print(num)
    num += 1
```

In this example, we initialize the **num** variable to 1 and then execute the loop as long as **num** is less than or equal to 5. Inside the loop we print the current value of **num** and then increment it by 1

# For loops

We use for loop when we want to iterate over a collection of items or when we know the exact number of times we want to execute a block of code

Here's the code for a for loop in python  
for variable in iterable:

    # code to execute

- **Variable** is a variable that represents the current item in the iterable that we're iterating over
- **iterable** is a collection of items that we want to iterate over, such as list, tuple, string, or range

Loop continues until we reach the last item in the sequence.

```
# list of numbers
```

```
numbers = [5, 6, 7, 3, 2, 1]
```

```
# iterate over the list
```

```
for val in numbers:
```

```
    print(val)
```

## Range Function:

- We can generate a sequence of numbers using **range()** function.
- `range(10)` will generate numbers from 0 to 9 (10 numbers)

# break and continue

- Loops iterate over a block of code until text expression is false, but sometimes we wish to terminate the current iteration or even the whole loop without checking test expression.

## **break statement:**

- The break statement terminates the loop containing it. Control of the program flows to the statement immediately after the body of the loop.
- If break statement is inside a nested loop (loop inside another loop), break will terminate the innermost loop.

for val in sequence:

# for loop code

if condition:

break

# for loop code

# outside loop code

while condition:

# while loop code

if condition:

break

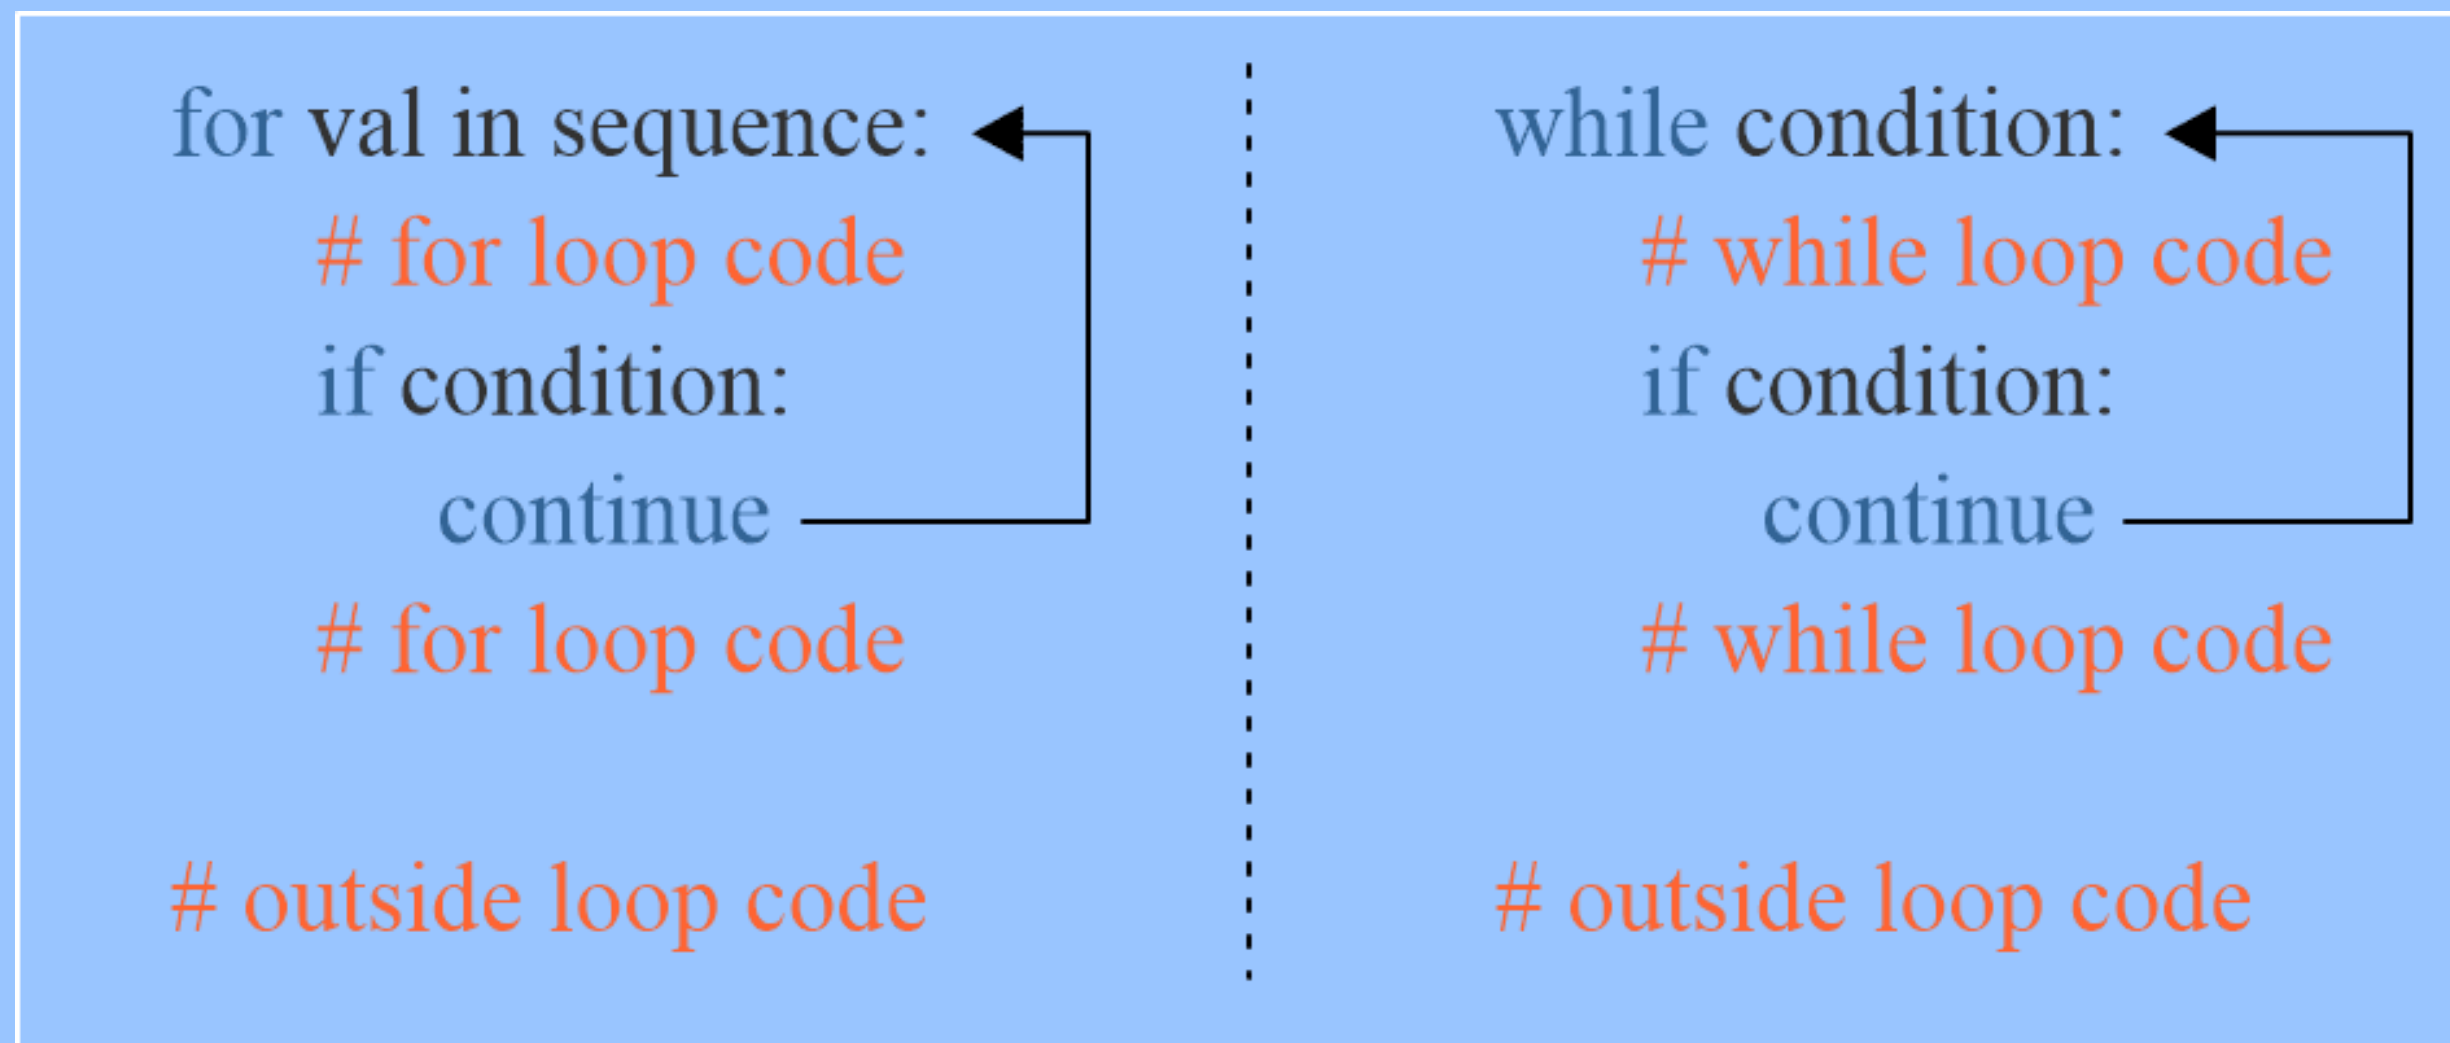

# while loop code

# outside loop code

## Continue Statement:

- The continue statement is used to skip the rest of the code inside a loop for the current iteration only. Loop does not terminate but continues on with the next iteration.

## Pass Statement

- Suppose we have a loop or a function that is not implemented yet, but we want to implement it in the future.
- They cannot have empty body.
- We use the pass statement to construct a body that does nothing.

# pass is just a placeholder for functionality to be added later.

```
sequence = {'p', 'a', 's', 's'}  
for val in sequence:  
    pass
```

# Let's Practice

- WAP to check if a number entered by the user is odd or even.
- WAP to find the greatest of 3 numbers entered by the user.
- WAP to check if a number is a multiple of 7 or not.
- WAP to find the sum of first n numbers. (using while)
- WAP to find the factorial of first n numbers. (using for)
- Ask the user to enter a number and check whether it is positive, negative, or zero.
- Take a number as input and print its multiplication table up to 10. (Assignment)
